Injectable candidate sealants for fetal membrane repair: bonding and toxicity in vitro

Bilic, G; Brubaker, C; Messersmith, P B; Mallik, A S; Quinn, T M; Haller, C; Done, E; Gucciardo, L; Zeisberger, S M; Zimmermann, R; Deprest, J; Zisch, A

Abstract: OBJECTIVE: This study was undertaken to test injectable surgical sealants that are biocompatible with fetal membranes and that are to be used eventually for the closure of iatrogenic membrane defects. STUDY DESIGN: Dermabond (Ethicon Inc, Norderstedt, Germany), Histoacryl (B. Braun GmbH, Tuttingen, Germany), and Tissucol (Baxter AG, Volketswil, Switzerland) fibrin glue, and 3 types of in situ forming poly(ethylene glycol)-based polymer hydrogels were tested for acute toxicity on direct contact with fetal membranes for 24 hours. For the determination of elution toxicity, extracts of sealants were incubated on amnion cell cultures for 72 hours. Bonding and toxicity was assessed through morphologic and/or biochemical analysis. RESULTS: Extracts of all adhesives were nontoxic for cultured cells. However, only Tissucol and 1 type of poly(ethylene glycol)-based hydrogel, which is a mussel-mimetic tissue adhesive, showed efficient, nondisruptive, nontoxic bonding to fetal membranes. Mussel-mimetic tissue adhesive that was applied over membrane defects that were created with a 3.5-mm trocar accomplished leak-proof closure that withstood membrane stretch in an in vitro model. CONCLUSION: A synthetic hydrogel-type tissue adhesive that merits further evaluation in vivo emerged as a potential sealing modality for iatrogenic membrane defects.

Dear Editors,

Also on behalf of my fellow authors, I hereby submit the manuscript entitled ‘Injectible candidate sealants for fetal membrane repair: bonding and toxicity ex vivo’ for your consideration for publication in American Journal of Obstetrics & Gynecology.

Iatrogenic preterm premature rupture of the fetal membranes is the ‘Achilles heel’ of fetoscopic interventions for prenatal surgery. Recent efforts have concentrated to take action before rupture rather than to react after obvious or symptomatic rupture. Along this lines, we introduce a novel injectible material sealant for fetal membrane repair that possesses appealing characteristics for preventive closure of fetoscopic entry sites. We show that this material is capable of sealing 3.5 mm trocar punctures in fetal membranes ex vivo.

This work has been presented orally at the 27th Annual International Fetal Medicine Surgery Society (IFMSS) meeting, Athenia Rivera, Greece, September 12-16, 2008.

Authorship:
I hereby confirm that all authors fulfill all requirements for authorship and approved submission.

Conflict of interest:
One of the authors of this paper, P.B. Messersmith, holds equity in Nerites Corporation, a company that develops surgical sealants and adhesives.

One test device in this study, the Cellerator, is marketed by Cytomec GmbH in which one of the authors (T.M. Quinn) holds equity.

Thank you very much for your editorial service to the fetal surgery community,
Sincerely,
Andreas Zisch

SUBMISSION CHECKLIST

American Journal of Obstetrics & Gynecology

The completed checklist must be uploaded upon submission. Submitted manuscripts without a fully completed checklist will not be considered. Checklist requirements are explained in detail in the Information for Authors (http://www.AJOG.org/authorinfo).

Instructions: Save the SUBMISSION CHECKLIST to your computer, address each item, and resave the file. Upload the newly saved checklist file from your computer along with the; cover letter, manuscript, tables, figures, suggested reviewers, and any other required documentation.

RE: Injectable candidate sealants for fetal membrane repair: Bonding and toxicity ex vivo

Corresponding author: Andreas H Zisch

General
☐ The manuscript, including all figures, tables, and required items, has been submitted online at www.ees.elsevier.com/ajog.
☐ The completed checklist is uploaded at the time of submission.
☐ The author(s) warrant that this submission is not currently under review by another journal.
☐ I attest that all authors have consulted the document Specific Inappropriate Acts in the Publication Process, which appears on the Journal website, and that all authors are in compliance.
☐ The word count of both the abstract and text (excluding references) appears in the lower left corner of the Title Page and is listed below:
  Abstract word count 153
  Text word count 3940
☐ The local institution as stated in the Materials and Methods section has approved human experimentation. Institutional Review Board Project #  SIV22/2006 'Plazenta und Nabelschnurblut als Quelle für Stamm/vorläuferzellen zur Gewebe- reparatur und zur Herstellung eines Wundeverschlusses bei vorzeitigem Blasensprung' was obtained on 8/16/2006 (date).
☐ The author(s) agree that Institutional Review Board approval documentation will be provided upon request.
☐ If the study was exempt from Institutional Review Board approval, an explanation is provided under Materials and Methods.
☐ Guidelines for the care and use of nonhuman animals or other species approved by the institution have been followed as indicated under Materials and Methods. The species is named in the Title, Abstract, Key Words, and Materials and Methods sections.
☐ The author(s) agree that upon request original data quoted or utilized in the submitted manuscript will be provided.

Trial/research type (check one)
☐ Randomized controlled trial: the CONSORT statement has been consulted. A flowchart as a figure is submitted in the manuscript.
☐ Meta-analysis or systematic review of randomized controlled trial: the QUOROM statement has been consulted.
☐ Meta-analysis or systematic review of observational studies: the MOOSE statement has been consulted.
☐ Diagnostic tests: the STARD Initiative has been consulted.
☐ Health economics: the checklist specific to Health Economics papers has been consulted and is submitted with the manuscript.
☐ Descriptive
☐ Case/control
☐ Prospective observational cohort
☐ Analysis of data from a prospective or retrospective database

Cover letter
☐ The cover letter with required information is included with the manuscript. Required information must include, but is not limited to:

Authorship, Conflicts of Interest, Previous Publications, and IRB approval.

Reviewers
☐ Names, addresses, and e-mail addresses of at least 3 suggested reviewers are included; as required for all article types, whether independent or society articles.

Authorship
☐ In the cover letter that accompanies the submitted manuscript, I have confirmed that all authors fulfilled all conditions required for authorship and approved the submission.

Conflict of interest
☐ The cover letter that accompanies the submitted manuscript addresses all potential conflicts of interest for each author as described in the Information for Authors.
☐ Are any authors either current or former employees of, or consultants to, a company whose product(s) is/are discussed in this article? If so, that information has been provided.
☐ Do any authors have stock or stock options in a company whose product(s) is/are discussed in this article? If so, I have stated the value of stock or stock options in the current market.
☐ Are any authors members of a speakers’ bureau for a company whose product(s) is/are discussed in this article? If so, I have stated this.

Previous or intended publication
☐ The submitted manuscript includes a reprint and/or a current copy of each article that the author(s) has/have previously published, submitted for possible publication, or presented in any manuscript form that discusses the same patients, animals, laboratory experiment, or data, in part or in full, as those reported in the submitted manuscript. Refer to the Information for Authors for detailed requirements (Ethics of the editorial process).
☐ Similarities, differences, and further explanations are provided in the cover letter that accompanies the submitted manuscript.

Previous submission (unpublished)
☐ Copies of previous peer review comments and a detailed response to each point has been included, if the author wishes.

Permissions
☐ Signed written permission from both the copyright holder and the original author for the use of tables, figures, or quotations previously published and their complete references are uploaded with the manuscript.
☐ Signed written permission for the use of quotations of personal communications and unpublished data has been obtained from the person(s) being quoted and is enclosed.
Basic Format
All elements of the manuscript are typed in English, double spaced, with a font size no smaller than 12, and 1-inch margins at the top, bottom, and sides.

All pages are numbered in the following order: title page, condensation, structured or unstructured abstract, body of the text, acknowledgments only of persons who have made substantive contributions to the study, references, figure legends, and tables.

Title page
The following elements are given in the following sequence:
- Title does not include any conclusion statements and is concise and suitable for indexing purposes.
- Author(s) name(s) and highest academic degree(s) are shown. Surnames appear in all capital letters: eg, Frederick P. ZUSPAN, MD.
- City or cities, state(s), and non-US countries in which the study was conducted are provided.
- The name(s) of the institution(s), section(s), division(s), and department(s) in/by which the study was performed are provided and the institutional affiliations(s) of the author(s) at the time of the study is/are indicated.
- If the findings have been presented at a meeting/conference, the name of the host organization/association, etc., is provided, as outlined in the Information for Authors.
- Acknowledgment of financial support is cited.
- Contact information for the individual responsible for reprint requests includes name and full mailing address, email address, or both, as the author wishes to be published in the Journal.
- If reprints will not be available, this has been stated on the title page.
- The corresponding author’s name, address, business and home telephone numbers, fax number, and email address have been provided.

Condensation
Page 2 of the manuscript is a single sentence of 25 words or less delineating the paper’s essential point(s) and double spaced.

Abstract and key words or short phrases
The abstract (structured or unstructured format) is double spaced with required margins on page 3 headed by the title and author’s or authors’ name(s). Below the abstract, 3 to 5 key words or short phrases are alphabetized.
- A structured abstract of 150 words or less is submitted as required for Research articles and Society Research articles. The abstract contains the 4 required major headings: Objective(s), Study Design, Results, and Conclusion(s), each with a brief presentation.
- An unstructured abstract is submitted as required, for Clinical Opinions (50 to 150 words) and Case Reports (maximum of 50 words), whether independent or society articles.

Text
Research articles have been organized into the following sections and identified with the following headings, as described in the Information for Authors:
- Introduction
- Materials and Methods
- Results
- Comment (structured as follows)
  - Brief Statement
  - Strengths and weaknesses of the study
  - Strengths and weaknesses in relation to other studies

Meaning of study
Unanswered questions and proposals for future research

References
Double spaced and inserted in the file without the use of automatic numbering software.
Numbered sequentially as they appear in the text.
Adhere to the format outlined in the Uniform Requirements for Manuscripts Submitted to Biomedical Journals. Examples shown in the Information for Authors have been followed.
Do not contain any personal communications or unpublished observations, which, if used, are mentioned parenthetically in the text, unnumbered. Signed written approval by the person being quoted is included with the submission.

Figures
Each figure has been uploaded separately and is not embedded in the manuscript text.
Each figure is numbered with an Arabic numeral and cited in numeric sequence in the text.
Each figure has a brief title.
Figure legends appear together on a separate page, not on the figure itself.
All patient identifying marks have been removed.
All patterns or shadings are distinguishable from each other. Lines, symbols, and letters are smooth and complete and do not contain freehand lettering.

Figure Legends
A 1- or 2- sentence description is provided for each figure; all legends are presented in numeric order on 1 page.
Each descriptive sentence is labeled with the corresponding figure number.
The legend page is numbered in sequence after the reference page(s).
Full credit is given to the original source of any copyrighted material.

Tables
Each table, headed by a title and numbered in Arabic numerals, is double spaced on a separate page.
Tables are cited in numeric sequence in the text.
Footnote symbols are used in the order noted in the AMA style guide.

Videos and computer graphics
The editors have been informed that the author has uploaded, or intends to submit a video or computer graphic.
A concise legend for each clip/graphic has been provided.
Materials are submitted in *.mpg or *.mov format.
Images adhere to Elsevier requirements for artwork at: http://www.elsevier.com/artwork

Out of a series of injectible sealants for fetal membranes, mussel-mimetic hydrogel adhesive was not toxic and capable of closing trocar punctures *ex vivo*. 
Injectible sealants for fetal membrane repair: Bonding and toxicity *in vitro*

Grozdana Bilic, Carrie Brubaker, Phillip B. Messersmith, Ajit S. Mallik, Thomas M. Quinn, Elisa Done, Leonardo Gucciardo, Steffen M. Zeisberger, Roland Zimmermann, Jan Deprest, and Andreas H. Zisch

**Objective:** This study was undertaken to test injectible surgical sealants that are biocompatible with fetal membranes, eventually for closure of iatrogenic membrane defects.

**Study Design:** Dermabond, Histoacryl, Tissucol fibrin glue, and three types of *in situ* forming poly(ethylene glycol)-based polymer hydrogels were tested for acute toxicity upon direct contact with fetal membranes for 24h. For determination of elution toxicity, extracts of sealants were incubated on amnion cell cultures for 72h. Bonding and toxicity was assessed through morphological and/or biochemical analysis.

**Results:** Extracts of all adhesives were non-toxic for cultured cells. However, only Tissucol and one type of poly(ethylene glycol)-based hydrogel, mussel-mimetic tissue adhesive, showed efficient, non-disruptive, non-toxic bonding to fetal membranes. Mussel-mimetic tissue adhesive applied over membrane defects created with a 3.5 mm trocar accomplished leak-proof closure that withstood membrane stretch in an *in vitro* model.

**Conclusion:**

A synthetic hydrogel-type tissue adhesive evolved as potential sealing modality for iatrogenic membrane defects that merits further evaluation *in vivo.*

**Key words:** fetal membranes, fetoscopy, iatrogenic PPROM, prophylactic plugging, tissue adhesive, fetoscopic access, fibrin, DOPA
Introduction

Invasive diagnostic and therapeutic fetal procedures are frequently complicated by amniotic fluid leakage, separation of amnion and chorion, or even frank iatrogenic preterm premature rupture of the fetal membranes (iPPROM). For fetoscopic procedures, rates of iPPROM range between 6 to 45%,\(^1\) but in a trial of fetal endoscopic tracheal occlusion for severe congenital diaphragmatic hernia a 100% rate was reported.\(^2\) Since these procedures are usually performed in the second trimester of pregnancy, iPPROM usually occurs at an early gestational age. Hence, the associated morbidity and mortality may compromise the expected benefits of the intervention. iPPROM is therefore a serious limitation for prenatal fetal surgery. Clinically, measures of plugging membranes after established rupture as well as of preventive plugging of fetoscopic access sites have been undertaken, as reviewed before.\(^3,4\)

For closure after obvious iatrogenic rupture, intra-amniotic injection at the puncture site of maternal platelets mixed with fibrin cryoprecipitate (‘amniopatch’) has evolved as promising route to seal.\(^5,6\) But increasing efforts have been concentrated on taking action \textit{before} rupture rather than reacting \textit{after} established or symptomatic rupture. Several preventive plugging methods using dry collagen and gelatin plugs or liquid blood-derived sealants have already been clinically investigated. Early experience encourages this avenue for prevention of iPPROM. A 2006 report on a 27 patient cohort found a low 4.2% rate of postoperative PROM upon gelatin plug (Gelfoam) insertion upon port retrieval in endoscopic fetal surgery.\(^7\) In another small clinical study, sequential injection of platelets, fibrin glue and powdered collagen slurry directly to the puncture site successfully prevented amniotic fluid loss after endoscopic procedure.\(^8\) Still, the positive outcome with these methods await to be reproduced in other centers. Of note, collagen fleece plugs (Lyostypt) are now routinely used for preventive plugging of membrane defects following fetoscopic endoluminal tracheal occlusion for in utero therapy of congenital diaphragmatic hernia in one center of the authors,
in Leuven. Other preventive plugging techniques such as scaffold-type plugs manufactured directly from decellularized amnion tissue have been so far only evaluated in animal models. Further, laser welding, and pre-emptive placement of synthetic surgical sealants before fetoscopic access were evaluated in vitro. There is evidence that spontaneous healing is slow, if not absent in fetal membranes. Histological follow-up of fetoscopic puncture defects in membranes of human patients several months after the procedure showed that the defects did not close by healing. The amnion layer contains few cells and lacks blood vessels completely, which makes healing response in this layer unlikely. Our own trials in rabbits of prophylactic plugging of membrane defects with decellularized amnion scaffolds showed effective sealing but without detectable signs of biological repair after a 1-week period, which is the maximum achievable in this experimental model. Recent studies in the midgestational rabbit observed signs of beginning healing of membrane defects upon addition of platelets or amniotic fluid cells to collagen plugs; the jury is still out whether this effect could assume relevant degrees of healing long-term. The main criteria for a prophylactic plug material may be to present an immediate, non-toxic and ideally, durable physical barrier to amniotic fluid, and not necessarily induction of biological healing. With this strategy in mind, we examined five liquid synthetic sealants, namely two types of cyanoacrylate glues and three poly (ethylene glycol-based) hydrogel-type polymers, for their principal aptitude for fetal membrane repair. Gluing of defective tissue in moist/wet conditions or even underwater presents a particular challenge. In the present study, we addressed gluing to moist, intact fetal membranes. Alkyl-cyanoacrylate glues were chosen on the basis of their well-known strong bonding to tissue, and their use as tissue adhesives in surgical and traumatic wound repair. Our choice of three synthetic poly (ethylene glycol) (PEG)-based hydrogel sealants, photopolymerizable gel, mussel-mimetic adhesive and commercial SprayGel was based on data showing their interfacial bonding to various tissues, and the possibility to deliver them in
minimally invasive liquid form for gelation in situ.\textsuperscript{17-19} Two types of PEG-based hydrogels under present study, SprayGel and photopolymerized PEG, were already used clinically. SprayGel has been clinically used as bioabsorbable anti-adhesion barrier in patients undergoing myomectomy.\textsuperscript{20} A clinically approved formulation of photopolymerized PEG hydrogel sealant, FocalSeal-L sealant, proved successful for closure of pulmonary air leaks in the lung occurring at cardiac operations.\textsuperscript{21} For the experimental mussel-mimetic adhesive hydrogel formulation of present study, no clinical data exist yet. Here we estimated applicability of these synthetic polymers as sealants on fetal membranes based on their bonding to fetal membranes and toxicity in vitro, using the biosurgical Tissucol fibrin glue sealant as internal reference.

\textbf{Material and methods}

\textbf{Membrane collection and amnion cell isolation}

The Ethical Committee of the District of Zurich approved the protocol (study Stv22/2006). A total of 15 fetal membranes were collected with written patient consent from elective caesarean sections. Mean gestational age was 38 ±1 weeks in the absence of labor, preterm rupture of membranes, chorioamnionitis, or chromosomal abnormalities. Fetal membrane pieces of 150-200 cm\textsuperscript{2} were collected. Human amnion epithelial (hAEC) and amnion mesenchymal cells (hAMC) were isolated and cultured as described previously.\textsuperscript{9}

\textbf{Sealants}

Alkyl-cyanoacrylate glue sealants: Dermabond (Ethicon Inc., Norderstedt, Germany) and Histoacryl (B. Braun GmbH, Tuttingen, Germany) are 2-octyl cyanoacrylate monomer and n-butyl-2-cyanoacrylate monomer, respectively. The formulations possess syrup-like viscosity. These glue act through anionic polymerization of hydroxyl groups from the minute
amounts of moisture normally present on actual surfaces that are glued, including biological surfaces. Indeed, cyanoacrylate glues are known to be extremely adhesive to tissue.\textsuperscript{16} Water act as a catalyst to accelerate this polymerization. The polymerization occurs within minutes after application to tissue. The resulting resin is waterresistant. Both Dermabond and Histoacryl are marketed as topical skin adhesives to hold skin edges of wounds from surgical incisions. As specified by the manufacturer of Dermabond, it is not for application on wet wounds.

Hydrogel sealants:

SprayGel (Confluent Surgical, Inc., Waltham, MA) is a sprayable anti-adhesion barrier polymer that consists of two synthetic liquid precursors that when mixed together, rapidly cross-link to form a solid absorbable hydrogel \textit{in situ}. The first precursor is a modified polyethylene glycol (PEG) with terminal electrophilic esters groups while the other precursor solution contains PEG that has nucleophilic amine groups.\textsuperscript{22} SprayGel is marketed outside the US for use in abdominal and pelvic surgical procedures. It has been clinically also tried to reduce adhesion formation after ovarian surgery.\textsuperscript{19} SprayGel was deposited at the fetal membranes through the air pump-assisted SprayGel Laparoscopic Sprayer. The gel is formulated to remain adherent on the site of application for approximately five days whereafter it is absorbed by way of gradual hydrolysis.

Photopolymerized PEG hydrogel sealant (pPEG) was formed via in situ interfacial photopolymerization of PEG diacrylate precursor of average molecular weight 700 Da (Sigma) according to a previously described gelation protocol.\textsuperscript{18} Fetal membranes were flushed with a tissue adsorbing photoinitiator eosin Y (1mM in 10mM 4-(2-hydroxyethyl)piperazine-1-ethanesulfonic acid, pH 7.4, 0.15M sodium chloride; (HEPES-buffered saline). Then solution containing 10% PEG diacrylate and the co-catalysts triethanolamine (13.2 \(\mu\)L/mL) and 1-vinyl-2- pyrrolidine (3.5\(\mu\)L/mL) in HEPES-buffered
saline was applied to the membranes and photopolymerized by irradiation at 480-520 nm and 75mW/cm² for 1 min from a portable Cermax xenon fiber optic light source, CXE300 (ILC Technology Inc., USA).

The mussel-mimetic tissue sealant is a catechol-functionalized poly(ethylene glycol) (cPEG) whose molecules crosslink into a hydrogel by way of oxidation after addition of sodium periodate. The composition and synthesis of cPEG is described elsewhere. For gelation, equal volumes of the polymer precursor solution (300 mg/mL in phosphate-buffered saline (PBS)) and the cross-linking solution (12 mg/mL sodium periodate in water) were mixed using a dual syringe applicator device equipped with a blending connector with mixer (FibriJet; Micromedics, Inc., St. Paul, MN). Hydrogels prepared from cPEG polymer and its derivatives are expected to possess the ability to secure very strong adhesion to almost any surface, even under wet conditions. The presence of catechol in cPEG sealant was inspired by the wet adhesive properties conferred by the catechol side chain of 3,4-dihydroxyphenylalanine (DOPA) amino acid, which is found in high concentrations in the foot proteins of marine or freshwater mussels.

Tissucol Duo S fibrin glue (Baxter AG, Volketwil, Switzerland) is a biological two-component adhesive that forms by mixing of human plasma cryoprecipitate solution with thrombin solution. The chemical and physical polymerization of the main component of fibrin glue sealant, fibrinogen, mimics the last step of the natural blood clot formation; Fibrin glue is clinically widely applied as hemostatic surgical sealant or adjunct to suture.

**Toxicity tests**

Toxicity of sealants for fetal membrane cells was evaluated using direct contact and elution tests, as per International Organization for Standardization (ISO) 10993-5 guidelines.

Direct contact cytotoxicity:
Direct contact studies were performed with term fetal membranes obtained from three cases. The amniotic layer was chosen for sealant application (Fig. 1A) because this layer was proposed to be the strength-bearing layer of fetal membranes and major determinant for PPROM.28 2x1cm patches of freshly harvested fetal membranes were placed into wells of 6-well plates with amnion layer up. The sealants were applied at 50µl and 200µl volumes except cPEG adhesive which was only tested at 200µl volume because of limited material. Membranes covered with sealant were covered with 3 mL culture medium (Ham’s F-12/DMEM supplemented with 10% FBS, 100 U/ml penicillin, and 100 µg/ml streptomycin) and cultured for 24h at 37°C. Controls were untreated membranes that were immediately processed for histology (control '0') or cultured for 24h (control '24'). After 24h, the treated membranes were fixed in 4% formaline, embedded in paraffin and sectioned for histology. Deparaffinized sections were either stained with hematoxylin-eosin (H/E), or stained for apoptotic cells using TUNEL technology (Terminal deoxynucleotidyl transferase dUTP nick end labeling; In Situ Cell Death Detection Kit, Fluorescein (Roche Diagnostics Gmbh, Mannheim, Germany). For total cell counts, all cell nuclei were counterstained with 4',6-diamidin-2'-phenylindol-dihydrochlorid (DAPI; Sigma, Buchs, Switzerland). The histologic images were taken with a Zeiss Axiovert 200M fluorescent microscope (Carl Zeiss, Goettingen, Germany) equipped with an Zeiss AxioCam MRe digital camera and analysed with AxioVision Rel. 4.5 software (Carl Zeiss). Apoptotic and total cell counts were acquired from fluorescence micrographs using automated image analysis software ImageJ 1.34s (National Institute of Health, Bethesda, ML). One tissue section per case was analysed, taking four optical fields per section for analysis.

Elution toxicity:
To test potential toxicity of soluble compounds released from the sealants for cultured amnion cells, two types of extractions were performed: First, extracts from sealant alone. For that, 0.2 mL of glue/hydrogel were incubated for 24h in 3 mL Ham's-F12/DMEM/FCS culture medium. Second, extracts from sealants applied to membranes. The second method was to resolve whether treatment of membranes could result in production of cytokines by hAECs and hAMCs that add to induction of apoptosis. For that 0.2 mL glue/hydrogel sealant were applied to 2 x 1 cm pieces of fetal membranes and incubated for 24h in 3 mL Ham's-F12/DMEM/FCS culture medium. The extracts were collected and stored at -80°C until use for culture. Amnion cells from four human cases were subjected for assay of toxicity, and for each sealant the extraction test was evaluated in triplicate. 2x10⁴ hAECs or hAMSCs were seeded per well of 48 well plates and cultured in Ham's/F12/DMEM/FCs standard medium near to confluence. Then medium was removed, and cells overlaid with 0.4 mL of extracts from either sealant alone, or extract from membranes+sealant. Extracts from untreated membrane samples from the same patients in standard culture medium served as controls. The cells were cultured for 72h. Cell morphology was assessed microscopically, and degree of cell detachment and lysis was judged qualitatively. Following evaluations were performed: (i) For total cell count, hAECs and hAMSCs were stained with DAPI (ii) Apoptotic cells were detected with in situ Cell Death Detection Kit (Roche). Total cell counts and apoptotic cell counts were acquired from fluorescence fluorescence micrographs using automated image analysis software ImageJ 1.34s (National Institute of Health, Bethesda, ML). (iii) Areas of individual cells were measured using LeicaQ Win Image Analysis software (Leica Imaging System Ltd, Cambridge, UK). (iv) Live/dead cell staining was performed. For that, amnion cell cultures were incubated for 3 min with a mix of calcein to detect live cells and ethidiumbromide homodimer to detect dead cells at 1µM and 2µg/ml, respectively. All
experiments were performed in triplicates and four optical fields were analysed for each sample.

**Sealing of fetal membranes lesion in vitro**

Sealing performance of cPEG adhesive was tested on trocar punctures through fresh fetal membranes. For that, wet fetal membranes were flat-mounted with the amnion side up on a commercial motorized mechanical stretch device named 'The Cellerator' (Cytomec GmbH, Switzerland; http://www.cytomec.com/) that we further adapted for use in fetal membrane studies (Fig. 4A). The Cellerator device permits fetal membranes expansion in a radial fashion keeping the strength of stretch uniformly distributed along the mounted membrane. Puncture lesions were created with a three-side pointed Ø 3.5mm trocar (Richard Wolf GmbH, Knittlingen, Germany). The punctured membranes were kept moistened with excess PBS, before approximately 0.5 mL cPEG adhesive was applied over the membrane defect. Two minutes after treatment, membranes were further stretched by about 30% of their original area. To demonstrate leak-proof sealing, the membranes, still mounted in the device, were overlaid with 0.3 L water. After the leak-proof test, the area of the treated membrane defect was excised and processed for standard histology. Histologic sealing was estimated microscopically from hematoxylin/eosin stained sections by the ability of the sealant to form a continuous bridge between the wound edges.

**Statistical analysis**

Data are shown as mean ± SEM. Two-tailed unpaired t test was performed using GraphPad Prism version 4.00 for Windows (GraphPad Software, San Diego, CA, USA). Significance level was set at $p<0.05$. 

Results

Contact-mediated effect of sealants for membrane morphology

Histology in figure 1 illustrates the effect of treatment for overall membrane morphology for the six bioadhesives under test. Fibrin glue and cPEG adhesive formed a continuous layer tightly bound to tissue (Figure 1B, arrow heads). The normal membrane morphology appeared maintained, with the amnion epithelial layer intact. SprayGel and pPEG exhibited partial or no binding to tissue, respectively. In the case of pPEG, we found the hydrogel layer sloughed into the culture medium shortly after immersion of the membranes in culture medium. Binding of Dermabond and Histoacryl to fetal membranes resulted in disruption of the amnion layer and change of overall membrane morphology, which was more pronounced for Dermabond. The effects of 50µl treatment volumes were very similar (not shown).

Direct contact-induced apoptosis

Fig. 2A depicts fluorescence micrographs of apoptotic cells (TUNEL) and all cell nuclei in tissue (DAPI) in fetal membranes treated with Dermabond. Fig. 2B gives the apoptosis rates for the 200µl test series. In untreated reference membranes, the apoptosis rate increased to 17±2% during the 24h incubation. Treatment with fibrin glue, cPEG adhesive, and pPEG did not enhance apoptosis over control. Dermabond and SprayGel treatment significantly (p< 0.05) enhanced apoptosis by 3.9-fold to 69±13 % and by 1.9-fold to 34±3% over the control, respectively. Histoacryl treatment produced a 1.6-fold increase of apoptosis rate to 28±6%, which was not significant over control. The outcome in the 50µl test series was similar, except that at lower dose, the apoptosis rate by SprayGel was not significantly over control (Fig. 2C).

Elution toxicity of sealants for primary cultures of amnion cells
To test for toxicity from compounds released from the sealants, we investigated cell lysis, cell detachment and change of cell shape in hAECs and hAMCs that were grown in extracts of sealants in culture medium. None of the cultures, except those grown in extracts of Dermabond, appeared affected by toxic compounds after 24h and 72h. There was no difference between extracts prepared from sealant alone, or from sealants applied to membranes. Fig. 3 depicts micrographs of hAECs and hAMCs cultures prepared from four fetal membranes after incubation with extracts of Dermabond. hAMSC were not affected in any condition as estimated by cell size and cell number. Only in the condition of hAECs grown in Demabond, we observed modest, insignificant reduction of cell size and number. Cell size of hAECs cultured in Dermabond extracts were $1138\pm166 \, \mu m^2$ (n=193 cells) versus $1423\pm196 \, \mu m^2$ (n=168 cells); cell numbers in the Dermabond condition were lower ($323\pm31$ cells/optical field) compared to control cultures ($424\pm47$ cells/optical field). TUNEL staining of hAEC and hAMC cultures did not show any induction of apoptosis, and live/dead staining with calcein and ethidium bromide showed that practically all cells in culture were alive (not shown). Overall, extracts of sealants behaved non-toxic for amnion primary cultures.

**Sealing of puncture lesions in vitro**

Our stratification revealed that cPEG adhesive and Tissucol fibrin glue alike show strong bonding to fetal membranes and behave non-toxic, which are two basic prerequisites for prospective application for repair. cPEG adhesive is a new formulation that has never been tested for sealing of membrane defects before. We tested 0.5 mL cPEG adhesive for closure of Ø 3.5mm trocar puncture wounds in fetal membranes mounted in a biomechanical test device (Fig. 4). Successful closure was achieved in all three test cases. Application of cPEG tissue adhesive over the defect resulted in an immediate leak-proof membrane seal that remained functional upon further radial stretch of the membranes. Fig. 4C shows
representative histologic images from two locations of a puncture lesion sealed with cPEG tissue adhesive. Histology confirmed that the cPEG tissue adhesive connected the wound edges over a distance of approximately 6 mm, which was the maximum diameter in such lesions. cPEG tissue adhesive was found adhered to both the amnion side, the application side in these experiments, but as well to the chorionic side of the membranes, Thus, sealant passed through the lesion and spread underneath the membranes.

Comment
Three commercial and two experimental synthetic sealants were tested along with Tissucol fibrin glue for applicability on fresh, moist human fetal membranes, using interfacial bonding and cytotoxicity in vitro for read out. Four of the five synthetic sealants failed to meet the combined requirements of membrane bonding and non-toxicity which excludes them for this type of repair. Our screen identifies one synthetic hydrogel, cPEG tissue adhesive, that exhibits bonding to membranes and non-toxic characteristics that favorably compare to fibrin glue. Ex vivo, cPEG adhesive demonstrated repair capacity for 3.5 mm trocar punctures, accomplishing immediate leak-proof sealing, which may warrant further evaluation in vivo. Membrane bonding properties of the six bioadhesives under this study demonstrated large variability. Cyanoacrylate-based glues seem inappropriate for application on fetal membranes. The observation of their strong bonding to fetal membrane tissue was accompanied by obvious damage to the amnion epithelial layer and disruption of membrane structure, especially the amnion layer. Amniotic integrity is considered more important than chorionic integrity because the amnion is thought to have greater tensile strength. In addition, Dermabond, but not Histoacryl, exhibited significant cytotoxicity. Two of the PEG-based hydrogel polymers, photopolymerizable PEG hydrogel and SprayGel, failed to bond to fetal membranes sufficiently. Photopolymerized PEG-diacrylate hydrogels were previously
used to create thin intravascular barriers to block thrombus deposition after balloon-induced arterial injuries in animal models, and firm adhesion of the PEG-diacrylate hydrogel to arterial walls was reported.\textsuperscript{18,29} Although the pPEG and SprayGel hydrogels could be polymerized on fetal membranes, they sloughed off from the membranes quickly after the immersion of the membranes in culture medium. Neither the hydrogel itself nor the one minute laser irradiation required for hydrogel curing produced adverse effects for membrane integrity. In the case of SprayGel, the resulting polymer layer was not continuous, weakly bonded to membranes, and cytotoxic.

cPEG adhesive, on the other hand, displayed membrane bonding and compatibility comparable to that of Tissucol fibrin glue. cPEG adhesive is a two-component, self-crosslinking polymer with the remarkable property to form strong and durable bonds to many surfaces even in wet environment. Creation of cPEG adhesive has been inspired by the composition of liquid adhesives secreted by marine mussels, which allow these organisms to firmly anchor themselves to any surface. The wet adherence of native mussel adhesive proteins rests on the unusual amino acid residue 3,4 dihydroxyphenylalanine (DOPA) that is present in high concentrations in the foot proteins of mussels.\textsuperscript{25,30,31} Work in the group of one of the authors (P.B.M.) and other laboratories has demonstrated that the wet adherence ability of mussel foot proteins can be conferred onto synthetic polymers by way of incorporating DOPA and DOPA analogues.\textsuperscript{17,23,32,33} Indeed, previous work has demonstrated that DOPA-functionalized PEG precursors cross-link via sodium periodate-mediated oxidation to form adhesive hydrogels with high rigidity.\textsuperscript{23} In the present study, the cPEG polymer contains a simplified mimic of DOPA in the form of a reactive catechol group, generating a new variation of the adhesive that can be used under the same preparative conditions.\textsuperscript{24} This formulation possesses both appealing and potentially problematic characteristics for use as fetal membrane sealant. Properties that we consider favorable are fast gelation (under a
minute); very slow hydrolysis over several months, allowing for durable sealing; and excellent tissue adhesion. Recent analysis revealed that bonds formed by a mussel-mimetic adhesive between porcine dermal tissues were several times stronger than those formed by fibrin glue. Possible disadvantages of the present formulation are the use of the strong oxidizing reagent sodium periodate as trigger of polymerization, which is known to be strongly irritating. However, a rapid chemical reaction ensues upon contact of periodate with pPEG, which ultimately gives rise to chemical crosslinking of the polymer but also results in reduction of periodate to less harmful oxidative species. Issues of in vivo irritation and inflammatory tissue response to cPEG adhesive are addressed in another study involving the use of cPEG for transplantation of mouse islets. While the results of that study, like the data reported herein, reveal favorable in vivo biocompatibility, ultimately the full effects of cPEG on uterine contractions and fetal survival and integrity will require further evaluation in the rabbit model of midgestation.

In summary, this study points to a new hydrogel formulation with appealing properties for membrane repair. Still, we are aware that such data ex vivo are limited in their ability to predict success in the in vivo situation.
