Teaching NeuroImages: Recurrent oculomotor palsies caused by neurosarcoidosis

A 53-year-old man presented with a recurrent left fourth nerve and acute left third nerve palsy (figure 1). Brain MRI showed leptomeningeal and oculomotor nerve contrast enhancement (figure 2). CSF examination indicated chronic lymphocytic meningitis with massively increased soluble interleukin (IL)-2 receptor and IL-6. Extensive infectious disease workup remained unremarkable. [18F]-Fluorodeoxyglucose (FDG)-PET/CT revealed active deep cervical lymph nodes containing noncaseating granulomas (figure 2). No pulmonary or other systemic manifestation was found, consistent with clinically isolated neurosarcoidosis. Upon immunosuppressive treatment, the oculomotor palsies rapidly remitted. Neurosarcoidosis is a rare condition lacking specific biomarkers. When suspected, FDG-PET/CT can guide diagnosis and prevent CNS biopsy.

AUTHOR CONTRIBUTIONS
V.K., J.A.P., K.I., A.C., C.G.-K., P.A., and M.L. were involved in the clinical management of the patient. V.K. wrote the manuscript. J.A.P., K.I., A.C., C.G.-K., P.A., and M.L. commented on the manuscript.

ACKNOWLEDGMENT
The authors thank the patient for consenting to the publication, the colleagues who were involved in treatment of the patient, and the photographers P. Bär and P. Breitschmid.

STUDY FUNDING
No targeted funding reported.

DISCLOSURE
V. Kana, J. Petersen, K. Ikenberg, A. Chappaz, C. Gerth-Kahlert, and P. Appenzeller report no disclosures relevant to the manuscript. M. Linnebank reports grants, personal fees, and nonfinancial support from Almirall, Bayer, Biogen, Genzyme, Merck, Novartis, and Teva outside the submitted work. Go to Neurology.org for full disclosures.
