A conserved role for SNX9-family members in the regulation of phagosome maturation during engulfment of apoptotic cells

Abstract

Clearance of apoptotic cells is of key importance during development, tissue homeostasis and wound healing in multi-cellular animals. Genetic studies in the nematode Caenorhabditis elegans have identified a set of genes involved in the early steps of cell clearance, in particular the recognition and internalization of apoptotic cells. A pathway that orchestrates the maturation of phagosomes containing ingested apoptotic cells in the worm has recently been described. However, many steps in this pathway remain elusive. Here we show that the C. elegans SNX9-family member LST-4 (lateral signaling target) and its closest mammalian orthologue SNX33 play an evolutionary conserved role during apoptotic cell corpse clearance. In lst-4 deficient worms, internalized apoptotic cells accumulated within non-acidified, DYN-1-positive but RAB-5-negative phagosomes. Genetically, we show that LST-4 functions at the same step as DYN-1 during corpse removal, upstream of the GTPase RAB-5. We further show that mammalian SNX33 rescue C. elegans lst-4 mutants and that overexpression of truncated SNX33 fragments interfered with phagosome maturation in a mammalian cell system. Taken together, our genetic and cell biological analyses suggest that LST-4 is recruited through a combined activity of DYN-1 and VPS-34 to the early phagosome membrane, where it cooperates with DYN-1 to promote recruitment/retention of RAB-5 on the early phagosomal membrane during cell corpse clearance. The functional conservation between LST-4 and SNX33 indicate that these early steps of apoptotic phagosome maturation are likely conserved through evolution.
A Conserved Role for SNX9-Family Members in the Regulation of Phagosome Maturation during Engulfment of Apoptotic Cells

Abstract

Clearance of apoptotic cells is of key importance during development, tissue homeostasis and wound healing in multicellular animals. Genetic studies in the nematode Caenorhabditis elegans have identified a set of genes involved in the early steps of cell clearance, in particular the recognition and internalization of apoptotic cells. A pathway that orchestrates the maturation of phagosomes containing ingested apoptotic cells is conserved through evolution. However, many steps in this pathway remain elusive. Here we show that the C. elegans SNX9-family member LST-4 orchestrates the maturation of phagosomes containing ingested apoptotic cells in the worm has recently been described. Mutants and overexpression of truncated SNX33 fragments interfered with phagosome maturation in a mammalian cell system. Taken together, our genetic and cell biological analyses suggest that LST-4 is recruited through a combined activity of DYN-1 and VPS-34 to the early phagosome membrane, where it cooperates with DYN-1 to promote recruitment/retention of RAB-5 on the early phagosomal membrane during cell corpse clearance. The functional conservation between LST-4 and SNX33 indicate that these early steps of apoptotic phagosome maturation are likely conserved through evolution.

Introduction

Apoptotic cell clearance is an important process during development, tissue homeostasis and wound healing [1,2]. The nematode C. elegans is a useful in vivo model to study programmed cell death and the clearance of apoptotic cells, as large numbers of cells die during embryonic development and during oogenesis in the adult germ line [3]. During clearance of apoptotic cells, two partially redundant pathways comprised of CED-1/MEGF10/LRP1, CED-6/GULP and CED-7/ABCA1, and of MIG-2/RhoG, UNC-73/Trio, CED-5/DOCK180 and CED-12/ELMO respectively, regulate the small GTPase CED-10/Rac, which in turn directs the actin polymerization and membrane extension required to engulf the dying cell [4]. CED-10/Rac activity during corpse engulfment is also regulated by ABL-1/Abi and its target ABI-1/Abi [5], the RacGAP SRGP-1 [6] as well as through a non-canonical Wnt pathway [7]. Following internalization, the two small GTPases RAB-5 and RAB-7, together with many additional factors, sequentially control the maturation of the nascent phagosome, ultimately leading to lysosome fusion and corpse degradation [8-13] for review see add [16,17]. How RAB-5 is recruited to early phagosomes is the subject of intensive study. We previously described an evolutionary conserved mechanism for the recruitment of RAB-5 to the early phagosome involving the large GTPase DYN-1/Dynamin and the phosphatidylinositol-3 kinase VPS-34 [18,10]. Zhou and colleagues recently extended these observations by demonstrating that the sorting nexin LST-4 also functions at this step, interacting physically with DYN-1 and promoting the fusion of the maturing phagosomes with endosomes and lysosomes [19]. In this study, we confirm these observations and extend our understanding of LST-4 function through a careful genetic and cell biological dissection of the early steps in phagosome maturation. We also show that a mammalian homologue of
LST-4 not only can rescue the *C. elegans* lst-4 mutant, but likely also is required for effective phagosome maturation in mammals. We thus propose that LST-4 constitutes another member of the evolutionarily conserved mechanism that drives early phagosome maturation following internalization of apoptotic cell corpses.

**Results**

**lst-4 controls maturation of apoptotic cell-containing phagosomes**

DYN-1 contains a C-terminal proline-rich domain [20], which has been shown to bind to the SH3 domain of various signaling molecules [21]. To identify potential SH3 domain-containing binding partner(s) for DYN-1 in the phagosome maturation process, we conducted a targeted RNAi screen of *C. elegans* genes coding for SH3 domain-containing proteins (Fig. S1, Table S1). This candidate-based RNAi screen identified a single gene, *lst-4* (lateral-signaling target) [22]. RNAi-mediated knockdown of *lst-4* led to a strong apoptotic cell corpse clearance defect (Fig. S1, Table S1). To confirm our RNAi results, we analyzed cell corpse clearance in animals carrying the *lst-4(tm2423)* mutation, a 212 bp deletion predicted to completely inactivate the gene (Fig. S2B). *lst-4(tm2423)* mutant worms showed a strong accumulation of non-acidified, AO-negative cell corpses in the hermaphrodite germline, a similar phenotype observed in dyn-1(834) mutants [10] (Fig. 1 A–D, S1), suggesting a defect in cell corpse clearance upstream of phagosome acidification.

LST-4 belongs to the family of sorting nexins, a rather heterogeneous group of proteins unified by the presence of a particular type of phospholipid binding domain, the phospholipase (PX) domain [23]. We confirmed by RT-PCR and sequencing the existence of two of the four predicted LST-4 isoforms, LST-4b and LST-4c, which are generated through the use of alternative promoters (Fig. S2A). Both variants contain a PX and a BAR domain [24]; however only LST-4c also contains an additional N-terminal SH3 domain [25] (Fig. 1i, S2A, C). LST-4 is the only *C. elegans* homolog of the mammalian SNX9/SNX18/SNX33 subfamily of sorting nexins, referred to as the SNX9-family member most similar to LST-4 (Fig. 1I), in the engulfing somatic sheath cells and observed a full rescue of *lst-4(tm2423)* mutants (Fig. 1J). This observation provides genetic evidence that the function of the SNX9-family member LST-4/SNX33 in cell corpse clearance is evolutionary conserved (see also below).

**LST-4/SNX33 co-localizes with DYN-1 on early phagosomes and is rapidly released upon RAB-5 recruitment**

To better understand at which stage of apoptotic cell processing/phagosome maturation LST-4 might play a role, we analyzed the subcellular distribution of LST-4::YFP during the engulfment process. In our rescuing lines, we observed that LST-4 localized in a patchy pattern around early (non-condensed, SYTO-negative) apoptotic germ cells (Fig. 2D–G), similar to DYN-1 localization [10,22]. These patches have been suggested to correspond to regions of extending tubules that attach and recruit surrounding endosomes and lysosomes [9,19]. LST-4 was not recruited to apoptotic germ cells in *ced-1(e1735)* or *ced-12(k149)* mutant animals (Fig. 2A–C'), indicating that recruitment occurs downstream of corpse internalization. We also performed co-localization studies to increase the temporal resolution of LST-4 recruitment during phagosome maturation. LST-4 co-localized extensively with actin and DYN-1 around apoptotic cells (Fig. 2H–K, R, S) but only minimally with RAB-5 (Fig. 2R, S) and not at all with RAB-7 (Fig. 2L–O, R, S). Taken together, these results indicate that engulfment signaling is required for LST-4 recruitment and suggest that both LST-4 and DYN-1 act at an early step of phagosome maturation (Fig. 2I–K) [10].

We next tested the genetic requirements for LST-4 localization during phagosome maturation (Figure 2P). Previous studies have shown that DYN-1 associates with VPS-34 and that these two proteins together play a key role in the recruitment of RAB-5 to early phagosomes containing apoptotic corpses. Recruitment of LST-4::YFP to phagosomes containing germ cell corpses was greatly diminished in *vps-34(ram4)* animals, suggesting that VPS-34 is required for efficient recruitment or maintenance of LST-4 on early phagosome membranes. To determine whether DYN-1 function is required for LST-4 recruitment, we compared subcellular localization of LST-4::YFP in *dyn-1(834)* animals at permissive and restrictive temperature. Whereas both germ cell corpse number and LST-4 localization were normal at the permissive temperature, we observed a large increase in LST-4-positive phagosomes at the restrictive temperature. A similar accumulation of LST-4-positive phagosomes was observed in *rab-5(ram4)* animals. By contrast, RNAi knockdown of *tub-7*, which acts at a later step in the phagosome maturation pathway, led to
Figure 1. LST-4 is required for efficient cell corpse clearance in the adult *C. elegans* germ line. (A–D). DIC micrographs (A–D) or epifluorescence pictures (A’–D’) of *C. elegans* germlines. Dorsal is to the top and the germline bend is to right. Arrowheads indicate apoptotic germ cells or Acridine Orange (AO) staining of apoptotic corpses. In wild-type worms (A, D’) and in mutants with increased levels of germline apoptosis such as *gla-3*(op216) (B, B’), AO preferentially stains engulfed apoptotic cells present in acidic compartments. In worms mutant for genes required for efficient removal of apoptotic cells, here *ced-12*(k149), refractile cell corpses persist but do not stain with AO (C, C’). Similarly, *lst-4(tm2423)* worms show increased persistent cell corpses that fail to stain with AO (D, D’). Size bar, 10 μm. (E–G) Transmission electron microscopy images of cell corpses and their neighboring cells (E–G) and corresponding camera lucida drawings (E’–G’); apoptotic cells are represented in dark grey, sheath cells in light grey and the germline syncytium in white. In *lst-4(tm2423)* animals (E, E’), apoptotic cells are fully internalized by the sheath cells, whereas in the *ced-1*(e1735); *ced-5*(n1812) double mutants apoptotic cells accumulate between germline syncytium and the sheath cells (F, F’). *gla-3*(op216) animals, which have increased germ cell apoptosis were used as a positive control (G, G’). Size bar, 2 μm. (H) Quantification of internalized apoptotic cells using TEM. For each genotype, two to three different animals 24 h post L4/adult molt were processed and analyzed as described by Zhou and coworkers [31]. (I) The domain structure of the SNX9 subfamily of sorting nexins is conserved through evolution. The percent aminoacid identity of each domain between LST-4 and human SNX18, mouse SNX33 and fly DSH3PX1 is indicated. SH3: Src- homology 3 domain; PX: Phagocytic oxidase domain; BAR: Bin/Amphiphysin/ Rvs domain. The tm2423 deletion results in a frame shift and a premature stop. (J) Expression of *C. elegans* LST-4 or mouse SNX33 in engulfing cells rescues the cell corpse clearance defect of *lst-4* mutants. Results shown are mean ± s.d. n=15 animals for each genotype.

doi:10.1371/journal.pone.0018325.g001
Figure 2. LST-4 is recruited to the early phagosome where it colocalizes with DYN-1 and RAB-5. (A–G) DIC micrographs (A–D) or epifluorescence pictures (A’–C’, E–G) of C. elegans germ lines. Arrowheads indicate early apoptotic germ cells or protein localized around apoptotic germ cells. LST-4 is recruited around the apoptotic cell during internalization (A’, E, G arrowhead) and highlights early, SYTO negative corpses (F). SYTO, like Acridine Orange, preferentially stains late-stage, internalized apoptotic cells. When the internalization process is disrupted, as in ced-1(e1735) (B, B’) and ced-12(k149) mutants (C, C’), LST-4 localization around apoptotic germ cells is lost (B’, C’ arrowheads). (H–O) DIC micrographs (H, L) or epifluorescence pictures (I–K, M–O) of C. elegans germ lines. LST-4::CFP (I, M) extensively colocalizes with DYN-1::YFP (J, K), but not with YFP::RAB-7 (N, O). (P) Localization of LST-4::YFP in different genetic backgrounds. Germ cell corpses and LST-4 positive phagosomes were quantified.
animals with normal numbers of LST-4-positive phagosomes, despite the accumulation of a large number of (late stage) phagosomes. These results suggest that loss of vps-34 arrests phagosomes at a very early step, prior to LST-4 recruitment, whereas inhibition of DYN-1 GTPase activity or loss of rap-5 arrest at a later, LST-4-positive stage of phagosome maturation.

We also performed a complementary set of experiments to determine the requirement for LST-4 in the recruitment of various other fluorescent reporters to the maturing phagosome. In the lst-4(tm2423) mutants, decreased recruitment was observed for the small GTPases RAB-5 and RAB-7, which have been previously shown to localize to early and late phagosomes respectively, as well as for the 2xFYVE::YFP reporter, which monitors VPS-34 activity [10] (Fig. 3B–H, I). By contrast, we observed an increase in CED-1 and in DYNein-positive phagosomes in lst-4 mutants, suggesting that DYN-1 recruitment to the phagosome membrane occurs independently of LST-4 function, and that in the absence of lst-4 function, phagosomes lacking arrest at an early, CED-1-positive and DYNein-positive, but RAB-5-negative stage of maturation (Fig. 3A–A’ E–E’, I). Taken together, these data indicate that LST-4 functions early in the phagosome maturation pathway, either together with or in parallel to DYNein-1, but upstream of RAB-5, VPS-34 activity and RAB-7 [Fig. 3K]. LST-4 is further required for the recruitment of RAB-5 to the maturing phagosome. Conversely, DYNein-1 activity, as well as recruitment or activation of RAB-5 is required for removal of LST-4 from phagosomal membranes.

**LST-4/SNX33 PX and SH3 domains are required for function in corpse degradation**

We next performed a structure/function analysis of LST-4/SNX33 during cell corpse clearance. Expression of mutant versions of LST-4, such as LST-4<sup>SH3</sup>, LST-4<sup>mutSH3</sup> and LST-4<sup>mutPX</sup> (bearing mutations in the SH3 or PX domain, Fig. 4A, 4E) could not rescue the lst-4(tm2423) persistent corpse phenotype (Fig. 4E–F). These results indicate that both the SH3 and PX domains of LST-4 are required for efficient phagosome maturation. Interestingly, we found that mutations in the SH3 domain did not affect LST-4 localization on the phagosome membrane (Fig. 4A–C’). In contrast, when we mutated the PX domain [33], LST-4 remained cytoplasmic and was no longer recruited to the phagosome. Thus, the putative interaction of DYNein-1 with the LST-4 SH3 domain, while essential for LST-4 function, is not required for LST-4 recruitment to the phagosome membrane. Rather, the dependence on the PX domain suggests that LST-4 might be recruited directly to the early phagosome membrane through lipid binding. This result implies a mode of recruitment of LST-4 and DYNein-1 during phagosome maturation that is distinct from the suggested mechanism of SNX9 recruitment during clathrin mediated endocytosis in mammals, where SNX9 and Dyn2 are recruited as a binary complex from the cytosol to the clathrin coat [26].

Since expression of mammalian SNX33 could rescue the phagosome maturation defect of *C. elegans* lst-4(tm2423) mutants, we surmised that SNX9-family members might also participate in mammalian apoptotic cell clearance. To test this hypothesis, we expressed various SNX33 constructs in NIH/3T3 fibroblasts and measured their ability to internalize and degrade apoptotic thymocytes. In contrast to control transfected NIH/3T3 cells, expression of YFP<sup>SNX33<sup>140-433</sup></sup> lacking the SH3 domain or YFP<sup>SNX33<sup>140-433</sup></sup> lacking the PX domain (Fig. 4G, I, J), significantly decreased the fraction of engulfed apoptotic thymocytes that were present within late (acidified) phagosomes (Fig. 4 G, K). Similar results were obtained through expression of the dominant negative constructs G<sup>FPRab5·SH3</sup> or Dyn2<sup>K44A</sup> (Fig. 4H, K). These results suggest that expression of truncated versions of SNX33 inhibits, directly or indirectly, the maturation of phagosomes containing internalized apoptotic cells.

**Discussion**

In this paper, we used a combination of genetic and cell biological studies in *C. elegans* to better define the function of the sorting nexin LST-4 in apoptotic cell corpse clearance. We also show, using transgenic rescue and mammalian cell culture experiments that the role of the LST-4/SNX-33 sorting nexin family in the maturation of apoptotic cell-containing phagosomes in conserved through evolution.

Our data suggest a model in which LST-4 and DYNein-1 are among the first proteins to be recruited to the nascent phagosome. Is it possible to order these two proteins? Our observation of the accumulation of DYNein-1-positive phagosomes in the adult gonad of *lst-4(tm2423)* clearly indicate that DYNein-1 can be recruited to phagosomes in the absence of LST-4 function (Figure 3). Lu et al. also observed recruitment of DYNein-1 to early phagosomes during embryonic development, albeit at a reduced efficiency [19].

These observations suggest that DYNein-1 is the first currently known protein to be recruited to the nascent phagosome.

Recruitment of LST-4 to phagosomes appears to be more complex. Although DYNein-1 and LST-4 are known to interact physically in both *C. elegans* and in mammals [19,34], we found that recruitment of LST-4 to phagosomes in *vivo* was dependent on the phosphoinositide-binding PX domain but not on the SH3 domain known to mediate interaction with DYNein-1 (Figure 4). Interaction with DYNein-1 (possibly via another interaction domain) might still be important however, as Lu and colleagues reported a complete lack of LST-4 recruitment in dyn-1(9) embryos, in which Dyn-1 fails to associate with phagosomes [19]. Surprisingly, we observed the opposite phenotype, namely an accumulation of LST-4-positive phagosomes in the gonad of animals carrying the dyn-1(ky51ts) mutation. This apparent contradiction can likely be resolved thanks to the recent discovery from the Zhou group that *dyn-1* mutants that fail to self-assemble (e.g., en9) have different set of phagosome maturation defects than those that are defective in GTP hydrolysis (such as *ky51*); whereas the former mutants fail to associate with phagosomes and prevent efficient recruitment of RAB-7, the latter mutants can bind to phagosomes, but fail to dissociate [13].

Based on these combined data, we propose that the physical presence of DYNein-1 on phagosomes likely is essential for recruitment of LST-4, either through a direct interaction via a domain other than the SH3 domain, or through activation of other factors required for LST-4 recruitment, such as VPS-34 (Figure 2, 4). Importantly, although the LST-4 SH3 domain is not required for recruitment of LST-4 to phagosomes, it is essential for LST-4 function, since LST-4 protein lacking the SH3 domain fails to rescue *lst-4(tm2423)* mutants.

Both our kinetic analysis of phagosome maturation in the adult gonad (Figure 2, [10]) and the time course studies by Zhou and colleagues [13,19,32] show that DYNein-1 and LST-4 only
Figure 3. LST-4 function is required for DYN-1(+) to RAB-5(+) progression during phagosome maturation. (A–H) DIC micrographs (A–H) or epifluorescence pictures (A’–H’) of wild type (A–D’) or lst-4 mutant worms (E–H’) carrying different fluorescent reporters. Arrowheads indicate early apoptotic germ cells or protein localized around apoptotic germ cells. Arrows denote late apoptotic germ cells or fluorescent halos formed around them. In both wild type (A’) and lst-4 mutants (E’) DYN-1::YFP is efficiently recruited to apoptotic cells whereas YFP::RAB-5 (B’, F’), YFP::2xFYVE (C’, G’) and YFP::RAB-7 (D’, H’) halos are less frequent in the gonad of lst-4(tm2423) mutant worms (F’, G’, H’ arrowheads) than in wild.
transiently associate with the maturing phagosome. We show above that dissociation of DYN-1 is dependent on LST-4 (Figure 3) and that conversely, dissociation of LST-4 requires a GTPase-competent DYN-1 (Figure 2). A similar relationship holds between LST-4, DYN-1, and the GTPase RAB-5: not only are both \textit{lst-4} and \textit{dyn-1} required for efficient recruitment to phagosomes (Figure 2, [10,19]), but both LST-4 and DYN-1 also fail to dissociate in the absence of RAB-5 (Figure 2, [10]). These observations suggest that LST-4 and DYN-1 coordinate, likely as part of a complex (Figure 4; [19]) RAB-5 recruitment. Once present on the phagosome, RAB-5 could then in turn, directly or indirectly, promote dissociation of DYN-1 and LST-1, possibly through promotion of DYN-1 GTPase activity [13].

The results presented here, together with previous data from our and other groups, suggest a sequential recruitment model for early phagosome maturation, where DYN-1 binds to and recruits VPS-34, which then through direct interaction and/or phosphoinositol-3-phosphate [PtdIns(3)P] production recruits LST-4 to the phagosome. Once on the phagosome surface, LST-4 interacts via its SH3 domain with DYN-1, generating an activated complex able to promote further maturation steps, including recruitment of RAB-5 and RAB-7. Finally, RAB-5 recruitment to and/or its activation on the early phagosome membrane likely promotes both the release of LST-4 and DYN-1 and progression through further downstream maturation events (Figure 5).

Interestingly, the degradation of apoptotic cells utilizes many genes that also function in receptor-mediated endocytosis, and their mutation can result in various human diseases (e.g., mammalian orthologues of RAB-5 in tuberous sclerosis, Dynamin-2 and Rab7 in Charcot-Marie-Tooth disease [35–37]).

Figure 4. Structure function analysis of LST-4/SNX33. (A–F) LST-4c constructs (A) were tested for their ability to rescue \textit{lst-4} mutants and for localization around internalized apoptotic cells (A–D). DIC (B–E) and epifluorescence images (B’–E’) of transgenic lines expressing LST-4c::YFP (B, B’), \textit{ash3} LST-4c::YFP (C, C’), \textit{mutSH3} LST-4c::YFP (D, D’) and \textit{mutPX} LST-4c::YFP (E, E’). (A) Schematic of LST-4c rescuing constructs. (F) Quantification of germ cell corpses and LST-4c::YFP halos around apoptotic cells in the corresponding genetic backgrounds. Animals were scored 24 h post L4/adult molt under DIC and epifluorescence. Data shown are means ± SD. n = 15 animals. Size bar, 10 μm. (G–K) The role of SNX33 in phagosome maturation is evolutionarily conserved. NIH/3T3 fibroblasts transfected with GFP (G), \textit{Rab5}^{	ext{D44A}} (H), \textit{SNX33}^{	ext{D140A-145S}} (I), \textit{SNX33}^{	ext{D140A-145S DD7A}} (J), or \textit{SNX33}^{	ext{D246A}} were incubated with apoptotic thymocytes (shown in blue) and Lysotracker Red LTR to determine the efficiency of phagosome maturation. Cells transfected with \textit{SNX33}^{	ext{D140A-145S DD7A}} showed decreased numbers of engulfed thymocytes (arrows) co-staining with Lysotracker Red. Size bar, 10 μm. The percentage internalized apoptotic phagosomes that were also Lysotracker positive (i.e., matured into acidic phagolysosomes) are shown in (K) (mean ± s.d., n = 3 experiments with 60 cells scored; only phagosomes in transfected [GFP(+) or HA(+) cells were scored).
Additionally, defects in phagocytic processes related to corpse removal result of autoimmune diseases and impaired neuronal function [31,38,39] and several players involved in this process have been implicated in pathogenesis of infectious agents [40–42]. Thus a better understanding of the molecular basis of apoptotic cell degradation could be of key importance to multiple aspects of normal cellular homeostasis and disease.

Methods

Nematode strains and reagents

Nematode strains were cultivated as described previously [27]. Mutations used were as follows: LG: gla-3(op216), ced-1(e1735); LGIII: ced-6(n1813), opEx110 (P*lm-7::yfp;unc-5); LG IV: lst-4(m2423), LGV: bcl-39 (P*lm-7::ced-1::gfp), LGX: dyn-1(ky51ts). The ky51 allele is a temperature-sensitive mutation in the GAPase domain of DYN-1, resulting in a rapid and reversible functional inactivation of the protein at the restrictive temperature [20]. Integration sites of opIs220 (P*cd-6::dyn-1::yfp, unc-119(+)), opIs223 (P*cd-6::zmy::unc-7, unc-119(+)), opIs202 (P*cd-7::zmy::unc-5, unc-119(+)), opIs436 (P*cd-7::lsmx::unc-119(+), unc-119(+)) – line1, opIs437 (P*cd-7::mSNX33::yfp, unc-119(+)) – line1, and opIs438 (P*cd-7::4t::ASH3::yfp, unc-119(+)) – line2 and opIs443 (P*cd-7::4t::ASH3::yfp, unc-119(+)) were not mapped. Unless noted otherwise, mutations were described previously [43]. opEx1401 (P*cd-7::lst-4::zmy, unc-119(+)), opEx1402 (P*cd-7::lst-4::zmy, unc-119(+)), opEx1430 (P*cd-7::4t::lst-4::zmy, unc-119(+)) – line1, opEx1465 (P*cd-7::lst-4::zmy, unc-119(+)) – line2, opEx1439 (P*cd-7::lst-4::zmy, unc-119(+)), opEx1443 (P*cd-7::lst-4::mutASH3::zmy, unc-119(+)) – line1, opEx1444 (P*cd-7::lst-4::mutASH3::zmy, unc-119(+)) – line2, opEx1445 (P*cd-7::lst-4::mutASH3::zmy, unc-119(+)) – line3, opEx1463 (P*cd-7::4t::mutPX::zmy, unc-119(+)) – line1, and opEx1464 (P*cd-7::4t::mutPX::zmy, unc-119(+)) – line2, were extrachromosomal arrays.

Reverse genetic screen

Feeding RNAi was performed as previously described [10]. Plates containing NGM-agarose, 200 mg/ml Ampicillin (Amp) and 2 mM IPTG (RNAi plates) were inoculated with 300 ml of appropriate bacterial cultures (transformed with constructs for generation of double stranded RNA under the control of the T7 promoter) and incubated for 8–12 hours before addition of worms. Between 30–60 synchronized gla-3(op216) L1-stage worms (gla-3 mutants have an increased number of apoptotic germ cells [44]) were placed on each RNAi plate and left for 72 h at 20°C [45]. Worms were then stained with acridine orange and apoptotic germ cells scored under an M2Bio Epifluorescence dissecting microscope (Zeiss). Positive candidates were retested and apoptotic germ cells scored directly by DIC microscopy.

DIC and immunofluorescence microscopy

Worms were placed on 2% agarose pads in M9, anaesthetized with levamisole (3–5 mM; Sigma) and mounted under a coverslip for observation using a Leica DM-RA microscope equipped with DIC (Normarski) optics and standard epifluorescence with filters appropriate for detection of YFP, CFP/SYTO41, SYTO59 or GFP. Images were false colored in OpenLab or Adobe Photoshop 11.0.1, which was also used to optimize brightness and contrast. Acridine orange (Molecular probes) staining was performed as described previously [46]. To observe engulfed cells, gonads were dissected in PBS supplemented with 12.5 µM of SYTO41 or SYTO59 (Invitrogen), incubated in the dark for 10 min and then scored under a fluorescence microscope.

Transmission electron microscopy

C. elegans grown on NGM agar plates were high-pressure frozen with an EM Pact2 (Leica Microsystems, Vienna, Austria) using flat specimen carriers with an indentation of 1.5 mm x 0.2 mm. The hole of the carrier (dedicated for pressure transmission) was filled with 1-hexadecene and the cavity of the transmission specimen was filled with 1-hexadecene and the cavity of the carrier with a droplet of PBS. C. elegans were picked from the agar plate and transferred to the PBS droplet. Subsequently, the majority of the buffer solution was drawn off with a filter paper leaving the worms in a small volume of buffer. 1-hexadecene was

---

**Figure 5. Model of early phagosome maturation.** 1. DYN-1 is recruited to nascent phagosomes and subsequently recruits VPS-34. 2a. VPS-34 in turn promotes the recruitment of LST-4 through direct interaction and/or the production of phosphatidylinositol-3 phosphates (open arrow) to which LST-4 binds via its PX domain. 2b. Membrane bound LST-4 associates physically with DYN-1 to generate an active complex that promotes RAB-5 recruitment and further phagosome maturation. 3. The presence of active RAB-5 on the phagosome membrane stimulates the inactivation and release of the DYN-1/LST-4 complex from mature phagosomes.
added on top and the specimen was frozen immediately. The frozen specimens were freeze-substituted in anhydrous acetone containing 2% OsO4 in a Leica EM AF52 freeze-substitution unit (Leica Microsystems). Specimens were kept successively at −90°C, −60°C, and at −30°C for 8 hours each. Temperatures were changed at a rate of 30°C per hour, finally reaching room temperature. After keeping the specimens at room temperature for 1 hour, OsO4 was removed by washing the specimens with anhydrous acetone twice. Subsequently, the specimens were gradually embedded in Epon/Araldite (Sigma-Aldrich, Buchs, Switzerland), 33% in anhydrous acetone overnight at 4°C, 66% in anhydrous acetone for 6 hours at 4°C and 100% for one hour at room temperature prior to polymerization at 60°C for 40 hours. Thin sections were stained with aqueous uranyl acetate 2% and Reynolds lead citrate and imaged in a Phillips CM 100 transmission electron microscope (FEI, Eindhoven, Netherlands) using a Gatan Orius CCD camera and digital micrograph acquisition software (Gatan GmbH, Munich, Germany).

**Generation of transgenic nematodes**

Transgenic worms were obtained by micro-particle bombardment in a Biolistic PDS-1000 (Bio-Rad) transformer as extrachromosomal arrays (opfEs) or low-copy chromosomal integrants (opfE alleles). unc-119 was used as a transformation marker. All lines were subsequently tested for rescue in the unc-119(e3) mutant background (see Results).

**Plasmid construction**

See additionally Table S1. Predicted isoforms of lst-4 (b and c) were amplified by RT-PCR from an N2 cDNA library using primers that added an AscI site upstream and an FseI site downstream of the coding sequence. PCR products were subcloned into pJET1/blunt or pJET1.2/blunt (Fermentas) and sequenced. The resulting plasmids (pJA17–18) were digested by AscI and FseI (New England Biolabs) and cloned into the bombardment vector: pLN180 (which contains cod1 promoter, a C-terminal yfp cassette and the 3′ untranslated region of lst-838) and pLN178 (as above, but with a C-terminal ecf cassette) to generate plasmid pJA20–21 and pJA36. SNX33 open reading frame was amplified from pcDNAs5/RT1/TOFLAG-mLST4 using the same strategy, to generate pJA42. A 4 kb Ptnu promoter region and 347 bp lst-4 3′UTR and downstream region were amplified from genomic N2 wild type DNA using primers which added for Ptnu a SmI and an AscI cassette up- and downstream of SpeI and Apal cassettes for lst-4 3′UTR respectively. The PCR products were cloned to generate pJA25 and pJA78. The SH3 deletion construct was performed using the forward primer lst-4_dSH3_AscI using pJA17 as a template, followed by cloning into pLN180 to generate pJA47. To generate mutations YDF8-10AA, W38A and Y55A in the SH3 domain of LST-4c, Dnpl-mediated site directed mutagenesis was performed starting from pJA17 using the oligos SDM_SH3_lst-4_d_1, 2 and 3. For the RYK265-7QA mutation in the PX domain of LST-4c, ligation PCR was performed using the oligos SDM6b_PXlst-4_d_bw and SDM6bPXlst-4_d(ev). The PCR products were subcloned into pJET1.2, confirmed and further cloned into either pJA20 or pJA78 to generate pJA54 and pJA68, respectively.

Mouse SNX33 cDNA was purchased from Open Biosystems; the full-length cDNA was amplified by PCR and cloned into pcDNAs-FLAG or pEBB-HA as a KpnI–NotI fragment. C-terminal truncation (SNX33(450)−573) and SNX33(34N) constructs were generated by PCR with appropriate primers. The N-terminal expression construct containing the SH3 domain (SNX33(1–369)) was created using an ApaI site to remove residues 91–574. pcDNA5-FLAG-Vps34 is described previously [47].

**Lysotracker acidification assay**

Cells were transfected using Lipofectamine 2000 as described previously [10], then washed and incubated in DMEM containing 10% fetal bovine serum (FBS) for approximately 6 h before the engulfment assay was conducted. Apoptotic thymocytes and Jurkat cells were generated as described previously [48]; apoptotic thymocytes (5.0×105 cells per condition) were stained with either CellTracker Violet (Invitrogen) and added to NIH/3T3 cells in 4-well Labtek II culture chambers (Fisher) followed by a brief centrifugation to pellet cells onto the slide. Thymocytes were allowed to be engulfed for 30 min; unbound apoptotic thymocytes were gently washed off with DMEM containing 10% FBS; slides were then incubated for 2 h in the presence of Lysotracker Red (1:10,000 dilution). Cells were then fixed with 3% paraformaldehyde (Sigma) in PBS for 30 min, permeabilized with 0.1% Triton X-100 (Sigma) and blocked with 5% skimmed milk that had been clarified by high speed centrifugation. Antibody staining was then performed as described previously [49]. Images were acquired using a Zeiss Axiosmager microscope with standard filtersets for YFP (Alexa 488 anti-GFP or Alexa 488 anti-HA, Invitrogen), CFP (CellTracker Violet) and Cy3 (Lysotracker Red, then deconvolved to remove out-of-plane light in AxioVision (Zeiss AG).
Figure S2 Alignment and molecular nature of lst-4 and its allele tm2423. (A) The C. elegans lst-4 locus is predicted to code for at least four different isoforms: lst-4a, lst-4b, lst-4c and lst-4d. We confirmed by RT-PCR amplification and subsequent sequencing of the exons/intron structure for the two isoforms lst-4b and lst-4c. Boxes represent exons; the regions coding for the SH3, the PX or the BAR domain are highlighted in grey, white boxes represent 3′ untranslated regions. Thin lines represent introns. tm2423 is a 212 bp deletion that results in a frame shift and premature termination (red bar). The positions of the primers used for genotyping tm2423 are indicated. (B) Genotyping of lst-4(tm2423) and wild type animals by PCR amplification. Primer sequences are described in Table S2. (C) Protein sequence alignment of C. elegans LST-4tc with human SNX18, mouse SNX33, and Drosophila DSH3PX1. All proteins contain a similar protein architecture consisting of a conserved N-terminal SH3 domain, a middle PX domain and a C-terminal BAR domain (indicated by thin lines). The thick line indicates the location of the tm2423 deletion. The tm2423 deletion results in truncated protein lacking the PX domain and the whole C-terminal part (Fig. II). (TIF)

Figure S3 Corpses are efficiently recognized and internalized in lst-4(tm2423) mutant worms. (A) DIC (A′–D′) and epifluorescence images of CED-1::GFP (A′, C′) and YFP::actin (D′) in wild-type (A, C) and lst-4 mutants (B, D). Arrowheads indicate apoptotic germ cells or protein around apoptotic germ cell. In lst-4(tm2423) mutants, the recruitment of CED-1::GFP (B′) and the reorganization of YFP::actin (D′) during engulfment appear normal. Size bar, 10 mm. (E, F) Quantification of germ cell corpses and CED-1::GFP (E) or YFP::actin halos (F) around apoptotic cells in the indicated genetic backgrounds. Animals were scored 24 h post L4/adult molt under DIC and epifluorescence. Data shown are means ± SD, n>15 animals. (TIF)

Table S1 List of C. elegans genes, encoding SH3-containing proteins, screened for suppression of AO staining. RNAi was performed in the gla-5(qp216) background (to assess suppression of AO) or in wild-type worms where applicable (to quantify persistent cell corpses) as described in materials and methods. Only RNAi against lst-4 was found to potently suppress AO staining of apoptotic germ cell corpses and to provoke a strong cell corpse accumulation in the C. elegans germline. The known SH3 domain containing engulfment genes cod-2 and cod-5 were not identified in this screen, likely due to the variable penetrance of feeding RNAi against these two genes. Clone source: Ahringer; plasmids from the Ahringer RNAi library [6]. pKD clones: genomic fragments from the gene of interest were PCR amplified and cloned into the RNAi feeding vector L4440. n.d., not done. (For Supplemental References see File S1). (TIF)

Table S2 List of Primers and Plasmids used in this study. (TIF)

File S1 Supplemental References. (DOCX)

Acknowledgments

We thank members of the Hengartner and Ravichandran laboratories for helpful input and suggestions. We thank Lukas Neukomm for pLN178 and pLN180 plasmids, Gery Barmettler and Therese Bruggmann from the center for microscopy and image analysis at the University of Zurich for TEM sample preparation and MichelLabouresse at the IGBMC Strasbourg for the EM worm freezing protocol. We thank Shohri Miiani for the lst-4(tm2423) mutant and the Caenorhabditis Genetic Center (CGC) for other strains used in this study.

Author Contributions

Wrote the paper: JA. Contributed to the generation of nematode transgenics, fluorescence microscopy studies and conducted the unbiased screen; JA KD. Performed the mammalian cell culture experiments; JMK. Performed high-pressure freezing and freeze substitution for TEM; AK JA. Performed transmission electron microscopy; JA. Contributed to editing of the manuscript: JA KD JMK AK KSR MOH. Contributed to the data analysis, project planning and writing of the manuscript: MOH KSR.
