Cerclage Cable-Plate System Periprosthetic Femoral Fracture THR

21

22 **Abstract:**

23 Objective: To ~~demonstrate-report~~ the successful use of cerclage cables around the
24 periprosthetic region of a femoral fracture ~~afterfollowing~~ total hip replacement (THR) ~~in~~
25 ~~a dog where sufficient with~~ bone stock ~~may not be available too limited~~ for other methods
26 of fixation.

27 Study Design: Case report

28 Animal: 6-year-old, Male Neutered, Golden Retriever.

29 Methods: ~~Acute onset of lameness due to failure~~ Locking plate fixation of a Type-B1
30 diaphyseal periprosthetic femoral fracture failed 14 days after cementless THR, and 6
31 days after initial femoral fracture repair. THR implants seemed unchanged on
32 radiographs, but lateral retraction of the screw-plate construct from the proximal segment
33 was evident. Bone stock was assessed as insufficient for adequate screw purchase,
34 prompting revision of the fixation with cerclage cable fixation of the proximal segment;
35 the cables were anchored to the original locking plate construct with threaded positioning
36 pins that screwed into the locking holes. Locking plate fixation failure for a Type-B1
37 diaphyseal periprosthetic femoral fracture that occurred 14 days after cementless THR,
38 and 6 days after femoral fracture repair. Radiographs revealed stable positions of the
39 THR implants, but screw loosening and separation of the plate fixation from the proximal
40 segment was evident. Given the lack of bone stock for adequate screw purchase, revision
41 of the fixation was performed by using cerclage cable fixation of the proximal segment;

Cerclage Cable-Plate System Periprosthetic Femoral Fracture THR

42 ~~the cables were anchored to the original locking plate construct with threaded positioning~~
43 ~~pins that screwed into the locking holes.~~

44 Results: Acceptable union was documented on radiographs by 3 months after revision.
45 No lameness and good range of motion of the hip were observed on clinical examination
46 13 months after surgery. Radiographs at 13 months documented static implant
47 positioning, and remodeling at the fracture site.~~Acceptable union was documented on~~
48 ~~radiographs by 3 months following revision. Clinical evaluation 13 months after revision~~
49 ~~of the failed fracture repair demonstrated no lameness and good range of motion of the~~
50 ~~hip.~~

51 Conclusion: Use of a cable-plate construct to stabilize a Type-B1 periprosthetic femoral
52 fracture led to successful long-term outcome in this dog.

53
54 Clinical significance: Use of a cable-plate construct may be considered to treat Type-B1
55 periprosthetic femoral fractures with limited bone stock

77

78 **Introduction**

79 Total Hip Replacement (THR) is a reliable treatment option for a variety of conditions
80 including canine hip dysplasia, hip osteoarthritis, and traumatic coxo-femoral luxation.¹⁻³

81 However, complications including septic or aseptic implant loosening, luxation,
82 infection, periprosthetic femoral fractures (PFF), and implant failure are well documented
83 following THR in dogs, and typically require surgical revision.⁴⁻⁸

84 Femoral fractures following THR in dogs has been reported in 1.5-13% of cases, with
85 most fractures occurring within the first 4 months after surgery.⁷⁻¹⁰ Risk factors reported

Cerclage Cable-Plate System Periprosthetic Femoral Fracture THR

86 for PFF include older age, cortical thinning, previous THR in contralateral limb, and dogs
87 with lower canal flare index (CFI).⁷⁻¹¹ Iatrogenic fissure fractures of the femur during the
88 reaming process of press-fit systems are routinely stabilized using cerclage wires with
89 high success.⁸⁻¹⁰ In contrast, post-operative PFF are typically far more difficult to
90 manage. Due to the anatomy of the proximal femur and the inherent design of most
91 intramedullary femoral implants, repair options are limited, and adequate screw purchase
92 may not be available in the proximal femur for plate-screw fixation. The increasing
93 prevalence in PFF reported in humans has led to the development of several guidelines
94 and a plethora of adjunctive fixation systems for the specific purpose of facilitating
95 fracture repair in these challenging cases.¹²⁻¹⁴ The incorporation of allograft struts,
96 specialized plates, and cerclage cable-plate constructs are routinely utilized.

97 In particular, stainless steel cerclage cables are often incorporated in conjunction with
98 plate-screw constructs to prevent screw-pull out, increase stability, and allow fixation of
99 the plate constructs around the proximal femur occupied by femoral stems where screw
100 purchase is limited.¹⁴ Implementation of cable-plate systems in veterinary medicine has
101 only been reported in a single horse.¹⁵ The purpose of this case report is to report
102 the describe— successful use of cerclage cables around the periprosthetic region of a
103 femoral fracture after total hip replacement (THR) in a dog with bone stock too limited
104 for other methods of fixation.~~the successful use of a cable plate system for the treatment~~
105 ~~of a failed PFF repair using conventional locking plate constructs in a dog.~~

121 **Clinical Report**

122 A 6-year-old, male neutered, Golden Retriever presented to the University of Florida

123 College of Veterinary Medicine Small Animal Hospital for an evaluation of a progressive

124 right hind limb lameness of several years duration. Additional medical history included a

Cerclage Cable-Plate System Periprosthetic Femoral Fracture THR

125 left cementless THR (BFX; BioMedtrix, Whyppany, NJ) (size 26mm acetabular cup, size
126 10 femoral stem, and 17mm +3 femoral head, with 4 cerclage wires due to intraoperative
127 fissuring of the femur) performed 3 years prior to presentation. Orthopedic examination
128 revealed a body condition score of 6/9, a grade 2/5,¹⁶ right hind limb lameness, moderate
129 muscular atrophy of the right hind limb, and moderate pain on extension and abduction of
130 the right hip.

131 Pre-operative radiographs revealed moderate right coxo-femoral osteoarthritis, moderate
132 to severe right coxo-femoral subluxation, moderate right pelvic limb muscular atrophy,
133 and static left THR implants. The CFI of the right femur was 1.93.¹⁰ Clinical signs were
134 attributed to severe hip dysplasia and osteoarthritis, and a right cementless THR was
135 performed using 26 mm cementless acetabular cup, size 9 collared cementless titanium
136 femoral stem and 17mm +3 femoral head (BFX; BioMedtrix).

137 During early preparation of the femoral canal, a fissure fracture developed at the cranio-
138 medial aspect of the proximal femoral metaphysis and diaphysis. Seven 1.0 mm single
139 loop cerclage wires were placed along and beyond the length of the fissure. The
140 remainder of the procedure was completed routinely, and post-operative radiographs
141 revealed satisfactory implant size and alignment (Fig. 1a, 1b). Standard multi-modal
142 analgesic protocols were followed (intravenous [IV] constant rate infusion of
143 Hydromorphone (Dilaudoid; Knoll Pharma), Lidocaine 2% (Vet One; Biose, ID) and
144 Ketamine Hydrochloride (Putney; Lostock Gralam, Northwich, UK). Cefazolin (30mg/kg
145 IV) was administered commencing one hour prior to surgery and every 90 minutes until
146 the end of surgery, then every 6 hours for 24 hours following surgery. Postoperative

Cerclage Cable-Plate System Periprosthetic Femoral Fracture THR

147 medications upon discharge consisted of oral 4.0 mg/kg tramadol hydrochloride every 8
148 hours, oral 2.0 mg/kg Carprofen (Zoetis; Parsippany, NJ) every 24 hours, and oral 29.5
149 mg/kg Cephalexin (Keflex; Teva Pharmaceuticals, Petach Tikva, Israel) every 12 hours
150 for 14 days.¹⁷

151 | One week later, the dog presented for an acute onset of a grade 4/5,¹⁶ right hind limb
152 lameness after slipping at home. Physical exam revealed swelling and pain over the
153 surgical site. Radiographs revealed a Vancouver Type B1 PFF, characterized by a stable
154 well-fixed stem with the fracture involving the distal tip of the stem at the mid-diaphysis.
155 ^{7,13} There was mild comminution, and cranial and medial angulation of the major distal
156 fracture segment, with a cerclage wire present within the fracture site. All remaining
157 implants were deemed to be unchanged when compared to the immediate post-operative
158 radiographs (Fig. 1c,1d).

159 Fracture repair was performed with plate fixation. A lateral approach was made to the
160 femur, the unstable cerclage wire at the fracture site was removed, and direct reduction of
161 the fracture was achieved with bone-holding forceps. A 14-hole 3.5 mm broad locking
162 | compression plate (DePuy Synthes; West Chester, PA) was applied in bridging fashion
163 (Fig 2a). The plate was contoured and applied to the lateral surface of the femur. One bi-
164 cortical 3.5 mm locking screw and one 3.5 mm bi-cortical cortical screw was used in the
165 greater trochanter, with one mono-cortical 3.5 mm cortical screw in the proximal
166 metaphysis. Three bi-cortical 3.5 mm locking screws and one 3.5 cortical screw were
167 used in the distal segment. Attempts to engage the trans-cortex of the proximal
168 metaphysis with the proximal screws were not successful due to interference from the

Cerclage Cable-Plate System Periprosthetic Femoral Fracture THR

169 femoral stem. Deep-tissue samples and the removed cerclage wire were submitted for
170 bacterial culture and sensitivity, which showed no evidence of growth. The same standard
171 multi-modal analgesic and anti-microbial protocols as the original THR procedure were
172 followed. Immediate post-operative radiographs revealed acceptable reduction and
173 implant placement; however, the proximal screws were deemed short and there was
174 immediate concern regarding the security of the proximal segment (Fig. 2a).

175 The dog was hospitalized during the initial convalescent period. On the sixth day of
176 hospitalization, the dog's ambulatory status declined, and a grade 3/5¹⁶ lameness of his
177 operated limb was noticed. Radiographs revealed lateral retraction of the screw-plate
178 construct from the bone, and a new short fracture line (Fig. 2b).

179 At this time, all radiographs were reviewed, and progressive osteopenia of the right femur
180 was noted, which was most evident when comparing radiographs performed three years
181 prior to immediately prior to right THR (Fig. 3a,3b). Systemic causes of osteopenia were
182 investigated after a serum ionized calcium concentration from a point of care blood
183 analyzer (iSTAT, Abbott; Princeton, NJ) was found to be elevated at 1.41 mmol/L
184 (reference range: 1.18-1.35 mmol/L). However, serum ionized calcium, parathyroid
185 hormone, Vitamin D, and parathyroid hormone-related protein performed by Michigan
186 State University Veterinary Diagnostic Laboratory were all within normal limits. Total
187 Thyroxine 4, Thyroid Stimulating Hormone, Free Thyroxine 4 results (1.45 µg/dL,
188 0.096ng/mL, 1.07ng/dL respectively), were also all within normal limits.

189 Revision surgery was planned to incorporate cerclage cable fixation to the failed
190 proximal construct segment. An approach was made to the proximal femur. The proximal

Cerclage Cable-Plate System Periprosthetic Femoral Fracture THR

191 locking screw was removed and tightening of the most proximal cortical screw in the
192 greater trochanter was attempted in order to restore reduction; however, the screw hole
193 was stripped. This cortical screw was then also removed. Two threaded positioning pins
194 (DePuy Synthes) were placed in the two most proximal screw holes, and two 1.7 mm
195 stainless steel cerclage cables (DePuy Synthes) were directed through the positioning
196 pins, placed circumferentially around the femur, then threaded through a pre-placed
197 metallic crimp (Fig. 4). A cable tensioner (DePuy Synthes) was used to sequentially
198 tighten both cables to approximately 40 kg of tension, thereby compressing the proximal
199 segment to the plate. The crimps were compressed to lock the cables in place. A third
200 cerclage positioning pin and 1.7 mm cable was placed in the 5th screw hole and secured in
201 similar fashion. The remaining proximal cortical screw was then tightened. A cancellous
202 autograft was harvested from the right proximal humerus and was transplanted into the
203 fracture site prior to routine closure. Post-operative radiographs revealed acceptable
204 reduction and implant placement (Fig 5). Similar standard multi-modal analgesic
205 protocols were followed as in the previous two surgical procedures. The dog was
206 discharged from the hospital 7 days after surgery.

207 At 30 days following the second revision, the dog was fully weight bearing on the right
208 hind limb with no observable lameness. Radiographs ~~showed~~ documented static implant
209 positioning, and remodeling at the fracture site consistent with healing. The dog was
210 reassessed at 12 weeks, 24 weeks, and 13 months after PFF revision. No further lameness
211 of the operated limb was detected. The implants in the right femur remained in position
212 and clinical union at the fracture site was confirmed by 12 weeks (Fig 6). The dog was

Cerclage Cable-Plate System Periprosthetic Femoral Fracture THR

213 | allowed to progressively return to normal activity over a 1-month period. Upon clinical
214 | evaluation 13 months after revision of the failed fracture repair, the dog had no lameness
215 | and good range of motion of the hip; owners reported that the dog had returned to normal
216 | activity levels and excellent limb use was reported. Radiographs at 13 months
217 | documented static implant positioning, and progression of remodeling at the fracture site
218 | (Fig 7).

Cerclage Cable-Plate System Periprosthetic Femoral Fracture THR

231

232

233 **Discussion**

234 This case report documents the successful treatment of a periprosthetic femoral fracture
235 after THR with a cable-plate system in a dog. These fractures are challenging because
236 bone stock in the proximal femur may be too limited for proper bone plate-screw
237 fixation. Treatment guidelines and available treatment options for PFF in dogs are
238 currently limited.^{7,10,18,19} The difficulty achieving sufficient screw purchase due to
239 crowding of the proximal femoral segment by the femoral stem was reflected in this case,
240 where implant failure was noted within one week of repair using a traditional plate-screw
241 construct.

Kommentar [JC1]: Reformatted to remove subordinate clause

242 The press-fit cementless femoral stem was elected due to a successful arthroplasty of the
243 contralateral side using the same system three years prior, current non-geriatric age, and
244 suitable CFI.¹⁰ The severity of osteopenia present was initially underestimated, and
245 strategies to prevent PFF and subsequent implant failure could have been implemented if
246 recognized earlier. Progressive osteopenia of the right femur was evident upon
247 comparison of cortical thickness from radiographs performed three years prior to
248 radiographs immediately prior to right THR (Fig 3a, 3b). Furthermore, the fissure
249 fractures encountered early in the broaching process should have alerted suspicion to the
250 poor mechanical integrity of the femur. The probable cause of osteopenia was determined
251 to be due to chronic disuse given the lack of evidence for endocrinopathies compromising

252 | bone quality. ~~While a~~ collared stem was chosen to prevent subsidence and excessive
253 | stress on the proximal metaphysis;²⁰ ~~however,~~ prophylactic plate placement should have
254 | been strongly considered at the time of initial arthroplasty.¹⁹ ~~A cemented femoral stem~~
255 | ~~could have been pursued, although fractures due to cortical thinning have also been~~
256 | ~~reported following cemented THR.~~⁷ ~~Alternatively, continued conservative management~~
257 | ~~for hip dysplasia rather than THR may have been a reasonable option given the~~
258 | ~~complexity of the case.~~

Kommentar [JC4]: Reformatted to remove subordinate clause

Kommentar [JC5]: Reformatted to remove subordinate clause

259 | ~~Periprosthetic fracture repair is also a major clinical challenge in the human field.~~¹²⁻¹⁴
260 | ~~Although no consensus of optimal technique or fixation system is currently~~
261 | ~~acknowledged, supplemental fixation to standard screw-plate internal fixation is often~~
262 | ~~necessary and routinely pursued.~~²¹⁻²³ ~~Screw-plate constructs provide greater mechanical~~
263 | ~~stability when compared to cable-plate systems in biomechanical analyses using healthy~~
264 | ~~human femurs and femoral models.~~^{12,21-23} ~~However, cable-plate constructs may be a more~~
265 | ~~suitable option for cases with poor bone quality and/or limited bone stock preventing~~
266 | ~~adequate screw purchase,²⁴ as screws may act as stress risers or pull out during cyclic~~
267 | ~~loading when in proximity to cement mantle or stem.~~²⁵

Kommentar [JC7]: Paragraph was relocated

268 | ~~Treatment options were limited in the case reported here.~~ ~~Additional screws in the lateral~~
269 | ~~plate could not have been used due to the presence of cerclage wiring, presence of a large~~
270 | ~~femoral stem, as well as poor bone quality.~~ ~~Fortunately, the bone plate system used for~~
271 | ~~the initial fracture repair was compatible with an orthopedic cable system (DePuy~~
272 | ~~Synthes). The system utilizes 316L stainless steel, titanium alloy, and L605 cobalt~~
273 | ~~chromium alloy cerclage cables that anchor to the plate and are placed under tension~~

Kommentar [JC8]: Reformatted to remove subordinate clause

Kommentar [JC9]: Reformatted to remove subordinate clause

Cerclage Cable-Plate System Periprosthetic Femoral Fracture THR

274 around the bone with the aid of a dedicated tensioner device. The ability to sequentially
275 tighten the cable by gradually applying tension was particularly useful in achieving
276 reduction of the fracture. ~~Although screw plate constructs have been shown to provide
277 greater mechanical stability when compared to cable plate systems in biomechanical
278 analyses using healthy human femurs and femoral models,^{12,21-23} cable plate constructs
279 may be a more suitable option for cases with poor bone quality and/or limited bone stock
280 preventing adequate screw purchase.²⁴ When in proximity to cement mantle or stem,
281 screws may act as stress risers, or pull out during cyclic loading.²⁵~~

282 The placement of circumferential cables around the trochanteric region enabled a
283 satisfactory level of fixation and stability without creating further defects in the
284 underlying bone. Successful clinical use of cable-plate systems has also been reported for
285 the treatment of Type B1 PPF in humans, ~~which is a common complication in geriatric
286 populations with poor bone quality.~~^{26,27} Contraindications to using cable-plate constructs
287 alone include loose or mal-aligned prostheses, in which arthroplasty revision is preferred,
288 as well as previous periosteal stripping or devascularization, as compression from the
289 cables may theoretically further delay bony union.^{28,29}

290 Alternative treatment options for this case included the addition of an orthogonal plate.³⁰
291 However, this would have been a poor choice due to bone stock availability and quality.
292 An additional plate would have likely achieved only monocortical fixation of the
293 proximal segment, and caused increased morbidity and tissue trauma due to the
294 additional exposure required for the placement of another plate. ~~Successful fixation with
295 string-of-pearls (SOP) plates has been described in dogs,¹⁸ but would have potentially led~~

Cerclage Cable-Plate System Periprosthetic Femoral Fracture THR

296 | to recurrent implant failure in this case. ~~Although t~~Temporary explantation and placement
297 | of a cemented stem could have allowed placement of bi-cortical screws in the
298 | periprosthetic region, but this was not favored due to the poor condition of the existing
299 | bone. The last available option involved permanent explantation in order to increase
300 | amount of available bone for fixation.

Kommentar [JC10]: Reformatted to remove subordinate clause

Kommentar [JC11]: Reformatted to remove subordinate clause

301 | The limitations of this report are inherent to the nature of being a single case. The
302 | outcome in this case ~~shows documents~~ the use of a cable-plate construct to successfully
303 | stabilize a Type-B1 PFF in a dog despite lack of life-long follow-up. The sequence of
304 | complications seen in this case suggests that pre-existing osteopenia requires a different
305 | approach from standard fractures. The poor mechanical characteristics of osteopenic bone
306 | may not offer enough pull-out strength for plate and screw fixation only, and a cable-
307 | plate construct may be indicated in these cases. Further studies and case inclusions are
308 | required to better define appropriate case selection in order to maximize treatment
309 | success in dogs with PFF following THR.

428 **Figure Legends**

Cerclage Cable-Plate System Periprosthetic Femoral Fracture THR

429 | Fig. 1 A) Craniocaudal and B) mediolateral projection radiographs of the right femur
430 | following THR. There is appropriate size and positioning of prosthetic femoral stem,
431 | femoral head, and acetabulum. Cerclage wires were placed around the proximal and mid-
432 | diaphysis of the right femur to address a femoral fissure that occurred during broaching.
433 | C) craniocaudal and D) mediolateral projection radiographs performed 1 week after THR
434 | revealed a comminuted mid-diaphyseal fracture characterized by cranial and medial
435 | angulation of the major distal fracture segment, with a cerclage wire present within the
436 | fracture margin. The femoral stem, acetabular cup, and six cerclage wires are unchanged.

437 | Fig 2 A) Craniocaudal projection radiograph immediately after open reduction and
438 | internal fixation ~~demonstrated~~ documenting acceptable reduction but suboptimal screw
439 | purchase in the proximal segment. B) Craniocaudal projection radiograph 6 days
440 | following fracture repair revealed fixation failure, as evident by gap formation between
441 | the plate and greater trochanter (black arrow) and collapse of the fracture site (black
442 | arrowhead)

443 | Fig. 3 A) Lateral projection radiograph of the right femur three years prior and B)
444 | immediately prior to THR. Note the development of cortical thinning evident by
445 | comparing the radiographs.

446 | Fig. 4 Intraoperative photograph of the proximal aspect of the surgical approach, prior to
447 | tensioning of the cable cerclage. A positioning pin was threaded into the locking portion
448 | of the screw hole (black arrow). A cable wire (white arrow) was passed circumferentially
449 | around the proximal femur, threading through the positioning pin, then the pre-placed
450 | crimp (grey arrow).

Cerclage Cable-Plate System Periprosthetic Femoral Fracture THR

451

452 Fig 5. A) Craniocaudal and B) mediolateral projection radiographs immediately
453 following revision with the cable system. Three cerclage cables (black arrows) secured
454 the proximal femoral metaphysis to the plate, which are linked to the plate via positioning
455 pins (white arrows). The THR implants are unchanged.

456

457 Fig 6. A) Craniocaudal and B) mediolateral projection radiographs 3 months following
458 revision with the cable system, ~~demonstrating documenting~~ no loss of reduction, stable
459 implants, and bony callus formation at the fracture site.

460

461 Fig 7. A) Craniocaudal and B) mediolateral projection radiographs 13 months following
462 revision with the cable system, documenting stable implants, and progressive remodeling
463 at the fracture site.
